About this document

These lecture notes were prepared by Max Hill for a 16-week linear algebra course (MATH 307) at University of Hawaii at Manoa in Fall 2025.

The textbook used is $Linear\ Algebra\ and\ Differential\ Equations\ (2002)$ by G. Peterson S. Sochacki, in which we cover primarily Chapters 1,2,5, and 6

0 Tentative Course Outline

- Weeks 1-3: Matrices and determinants. (Systems of linear equations, matrices, matrix operations, inverse matrices, special matrices and their properties, and determinants.)
 - Section 1.1: Systems of Linear Equations
 - Section 1.2: Matrices and Matrix Operations
 - Section 1.3: Inverses of Matrices
 - Section 1.4: Special Matrices and Additional Properties of Matrices
 - Section 1.5: Determinants
 - Section 1.6: Further Properties of Determinants
 - Section 1.7: Proofs of Theorems on Determinants
- Weeks 4-6: Vector spaces. (Vector spaces, subspaces, spanning sets, linear independence, bases, dimension, null space, row and column spaces, Wronskian.)
 - Section 2.1: Vector Spaces
 - Section 2.2: Subspaces and Spanning Sets
 - Section 2.3: Linear Independence and Bases
 - Section 2.4: Dimension; Nullspace, Rowspace, and Column Space
 - Section 2.5: Wronskians
- Weeks 7-11: Linear transformations, spectral theory. (Linear transformation, eigenvalues and eigenvectors, algebra of linear transformations, matrices for linear transformations, eigenvalues and eigenvectors, similar matrices, diagonalization, Jordan normal form.)
 - Section 5.1: Linear Transformations
 - Section 5.2: The Algebra of Linear Transformations
 - Section 5.3: Matrices for Linear Transformations
 - Section 5.4: Eigenvalues and Eigenvectors of Matrices
 - Section 5.5: Similar Matrices, Diagonalization, and Jordan Canonical Form
 - Section 5.6: Eigenvectors and Eigenvalues of Linear Transformations

• Midterm Exam

- Weeks 12-14: Systems of differential equations. (Theory of systems of linear differential equations, homogeneous systems with constant coefficients, the diagonalizable case, nonhomogeneous linear systems, applications to 2 × 2 and 3 × 3 systems of nonlinear differential equations.)
 - Section 6.1: The Theory of Systems of Linear Differential Equations
 - Section 6.2: Homogenous Systems with Constant Coefficients: The Diagonalizable Case
 - Section 6.3: Homogenous Systems with Constant Coefficients: The Nondiagonalizable Case
 - Section 6.4: Nonhomogeneous Linear Systems
 - Section 6.6: Applications Involving Systems of Linear Differential Equations
 - Section 6.7: 2×2 Systems of Nonlinear Differential Equations
- Weeks 14-16: Other stuff if time allows. (Converting differential equations to first order systems (section 6.5), linearization of 2 × 2 nonlinear systems (???), stability and instability (section 6.7), predator-prey equations (section 6.7.1).)
- Final Exam

1 2025-08-25 | Week 01 | Lecture 01

This lecture is based on textbook section 1.1. Introduction to Systems of Linear Equations

The nexus question of this lecture: What is a system of linear equations, and what does it mean to 'solve' a system of linear equations?

1.1 A first example of a system of linear equations

We begin with something concrete.

Example 1 (A first example of a system of linear equations). Consider the following word problem:

A boat travels between two ports on a river 48 miles apart. When traveling downstream (i.e., with the current), the trip takes 4 hours, but when traveling upstream (i.e., fighting the current), the trip takes 6 hours.

Assume that the boat and the current are both moving at a constant speed. What is the speed of the boat in still water, and what is the speed of the current?

This problem is hard to reason through without writing something down, but becomes much simpler when we formalize it mathematically with equations. The unknowns are (1) the speed of the boat in still water and (2) the speed of the current. So let

$$x :=$$
(the speed of the boat in still water) $y :=$ (the speed of the current).

The speed of the boat going downstream is x + y. Therefore, since (speed) \times (time) = (distance travelled), we have

$$4(x+y) = 48$$
, or equivalently $x+y = 12$.

Similarly, the sped of the boat going upstream is x - y, so

$$6(x-y)=48$$
, or equivalently $x-y=8$

Thus, we have the following system of linear equations:

$$\begin{cases} x+y=12\\ x-y=8. \end{cases} \tag{1}$$

This system has **two equations** and **two variables** (x and y). You have encountered systems of equations like this many times. With the help of the technology of algebra, solving this problem (namely, solving System (1)) is much easier than solving the original word problem.

- In this case, the problem can be easily solved **algebraically** using a substitution (e.g., plug x = 8 + y into the first equation and solve for y, then solve for x after finding y). This gives the solution (x, y) = (10, 2). The speed of the boat in still water is 10mph. The speed of the river current is 2mph.
- We can conceive of another type of solution, which uses a **geometric**, rather than algebraic perspective: observe that each equation x + y = 12 and x y = 8 represents a line on the xy-plane. Plot the lines. Their intersection is the point (10, 2), which is the solution.
- However, solving systems of equations like in (1) becomes more cumbersome when there are lots of variables and equations. Doing substitutions and algebraic manipulations will still work, but will be tedius and difficult if you have many equations and variables.

Later, we will introduce a general algorithm which can solve any such system. This algorithm is called *Gauss-Jordan elimination*, and it will be one of the core techniques that we will use to solve many types of problems in this class.

End of Example 1. \square

1.2 Key definitions: linear systems and their solutions

In this section, we formalize the mathematical objects we are studying.

Definition 2 (Linear equation). A *linear equation* in the variables x_1, \ldots, x_n is an equation that can be written in the form

$$a_1x_1 + a_2x_2 + \ldots + a_nx_n = b,$$

where a_1, \ldots, a_n and b are constants (e.g., fixed real numbers). The numbers a_1, \ldots, a_n are called **coefficients**.

Note that the variables x_1, \ldots, x_n are not raised to any powers. That's what makes the equation *linear*. If we had squares or cubes of some of the x_i 's, or products like x_1x_3 , then the equation would be quadratic or cubic, or something else, but not linear.

Example 3 (Examples of linear equations).

• The equation

$$2x - 3y = 1$$

is a linear equation in the variables x and y. Its graph is a line on the xy-plane.

• The equation

$$3x - y + 2z = 9$$

is a linear equation in the variables x, y and z. Its graph is a plane in 3-dimensional space (denoted \mathbb{R}^3).

• The equation

$$-x_1 + 5x_2 + \pi^2 x_3 + \sqrt{2}x_4 = e^2$$

is a linear equation in the variables x_1, x_2, x_3 , and x_4 . The coefficients are

$$a_1 = -1$$
, $a_2 = 5$, $a_3 = \pi$, and $a_4 = \sqrt{2}$.

The graph of this linear system is a 3-dimensional hyperplane in 4d-space (i.e., \mathbb{R}^4).

Observation: There is a simple relationship between the number of variables and the dimension of the graph:

dimension of graph =
$$(\# \text{ of variables}) - 1$$
.

End of Example 3. \square

Definition 4 (Linear system, solution of a linear system). When considered together, a collection of m linear equations

$$\begin{cases}
 a_{11}x_1 + a_{12}x_2 + \dots + a_{1n}x_n = b_1 \\
 a_{21}x_1 + a_{21}x_2 + \dots + a_{2n}x_n = b_2 \\
 \vdots \\
 a_{m1}x_1 + a_{m2}x_2 + \dots + a_{mn}x_n = b_m
\end{cases}$$
(2)

is called a **system of linear equations**, or **linear system** for short. A **solution** to a system of linear equations is a set of values for x_1, \ldots, x_n which satisfy all equations in system (2).

Example 5 (A system of linear equations). An example of a system of linear equations is

$$\begin{cases} x - y + z = 0 \\ 2x - 3y + 4z = -2 \\ -2x - y + z = 7 \end{cases}$$

When a linear system like this walks in the door, we always first ask two basic questions: (1) 'how many equations does it have?' and (2) 'how many variables does it have?'. In this case, we have m = 3 equations and n = 3 variables.

End of Example 5. \square

1.3 How to understand solutions of linear systems geometrically

Here is a very useful geometric perspective. In system (2), we have a system of m equations expressed in n variables x_1, \ldots, x_n . Each of the m equations is the equation of some hyperplane¹ which lives in n-dimensional space (\mathbb{R}^n). The solution to the linear system is the intersection of these hyperplanes.

For example, in Example 5, the 'hyperplanes' were lines, and their intersection was the point (x, y) = (10, 2).

We will spend a lot of time understanding what hyperplanes look like, and what intersections of hyperplanes look like.

¹Note: Hyperplanes will be defined more formally later, but for now can be thought of as generalized lines or planes, since a 1-dimensional hyperplanes is a *line* and a 2-dimensional hyperplane is a *plane*.

2 2025-08-27

2.1 How to understand solutions of linear systems geometrically

Here is a very useful geometric perspective. In system (2), we have a system of m equations expressed in n variables x_1, \ldots, x_n . Each of the m equations is the equation of some hyperplane² which lives in n-dimensional space (\mathbb{R}^n). The solution to the linear system is the intersection of these hyperplanes.

The clearest example of this can be seen in the linear system:

$$\begin{cases}
 a_{11}x + a_{12}y = b_1 \\
 a_{21}x + a_{22}y = b_2
\end{cases}$$
(3)

where $a_{12}, a_{22} \neq 0$. (In this case, the "hyperplanes" are simply lines.) Here, the solutions to the first equation are the points on the line

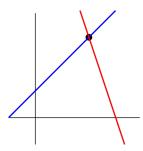

$$y = -\frac{a_{11}}{a_{12}}x + b_1. (4)$$

Similarly, the solutions to the second equation are the points on the line

$$y = -\frac{a_{21}}{a_{22}}x + b_2. (5)$$

There are three possible things that can happen when we intersect the two lines in Eqs. (4) and (5):

• Case 1. The two line equations Eqs. (4) and (5) represent distinct lines and are not parallel. In this case, their intersection consists of a unique point, like this:

In this case, the system (3) has **exactly one solution**—namely, the intersection of the two lines, just like we saw in the boat example.

- Case 2. The two line equations Eqs. (4) and (5) represent two parallel but different lines. In this case, the two lines never intersect each other (i.e., there is no point that lies on both lines), so the system (3) has no solutions.
- Case 3. The two equations of lines are the same, so they represent the same line. Therefore the intersection of the two lines is the entire line. Therefore, there are **infinitely many** solutions to the linear system (3). Namly, any point (x, y) on the line is a solution to the linear system.

These three cases constitute the following trichotomy:

Fact: A system of linear equations either has (1) exactly one solution, (2) no solution, or (3) infinitely many solutions.

We haven't proven this fact, only illustrated it for systems of linear equations like (3) that have 2 equations and 2 variables. In fact, as we shall see, this fact always holds for all linear systems of the form given in (2), no matter how many equations and variables.

²Note: Hyperplanes will be defined more formally later, but for now can be thought of as generalized lines or planes, since a 1-dimensional hyperplanes is a *line* and a 2-dimensional hyperplane is a *plane*.

2.2 Gauss-Jordan Elimination

The nexus question of this lecture: What is Gauss-Jordan elimination?

In this lecture, we will introduce *Gauss-Jordan elimination*, a general algorithm which can be used to solve any system of linear equations.

Suppose we wish to solve the following system:

$$\begin{cases} x - y + z = 0 \\ 2x - 3y + 4z = -2 \\ -2x - y + z = 7 \end{cases}$$
 (6)

This system has 3 equations and 3 variables x, y and z. Suppose that we know ahead of time that this system has a unique solution (it does). Then, in principle, we could solve this using substitution, but that would suck. Instead, we shall iteratively transform this linear system into successively simpler systems until we get to a point where the solution is obvious.

To do this, we shall utilize three types of transformations, called *elementary operations*, to wit:

- 1. Interchange two equations in the system.
- 2. Multiply an equation by a nonzero number.
- 3. Replace an equation by itself plus a multiple of another equation.

Two systems of equations are said to be *equivalent* if they have the same solutions. Applying elementary operations always results in an equivalent system. We'll use some combination of these operations to produce a system of the form

$$\begin{cases} x = * \\ y = * \\ z = * \end{cases}$$

where each * is a constant which we will have computed. This will be our solution to the linear system (6), because the two systems are equivalent.

Input: A system of linear equations of the form given in (2), such as the following:

$$\begin{cases} x - y + z = 0 \\ 2x - 3y + 4z = -2 \\ -2x - y + z = 7 \end{cases}$$
 (7)

Output: If a unique solution exists, then the output will be a solution of the form

$$\begin{cases} x = * \\ y = * \\ z = * \end{cases}$$

Steps: We initialize the algorithm by setting up an *augmented matrix* corresponding to the system. For the system in (6), the augmented matrix is

$$\left[\begin{array}{ccc|c}
1 & -1 & 1 & 0 \\
2 & -3 & 4 & -2 \\
-2 & -1 & 1 & 7
\end{array}\right].$$

Comparing this with system (6), it becomes clear that the augmented matrix was obtained essentially by just erasing the variables x, y, and z in (6), and then placing what remains into an array. We also drew a vertical line to the separate the left- and right-hand sides of the equations.

7

- The matrix to the left of the vertical row is called the *coefficient matrix*.
- A line of numbers going from left to right is called a **row** of the matrix. A line of numbers going down the matrix is a **column**.

Gauss-Jordan elimination is like a game where the player has three possible moves, called **row operations**:

- 1. Interchange two rows.
- 2. Multiply a row by a nonzero number.
- 3. Replace a row by itself plus a multiple of another row.

The player does row operations with the **goal** of making as many numbers in the coefficient matrix zero as possible.

$$\begin{bmatrix} 1 & -1 & 1 & | & 0 \\ 2 & -3 & 4 & | & -2 \\ -2 & -1 & 1 & | & 7 \end{bmatrix} \xrightarrow{R_2 - 2R_1} \begin{bmatrix} 1 & -1 & 1 & | & 0 \\ \mathbf{0} & -\mathbf{1} & \mathbf{2} & | & -\mathbf{2} \\ -2 & -1 & 1 & | & 7 \end{bmatrix} \xrightarrow{R_3 + 2R_1} \begin{bmatrix} 1 & -1 & 1 & | & 0 \\ 0 & -1 & 2 & | & -2 \\ \mathbf{0} & -\mathbf{3} & \mathbf{3} & | & 7 \end{bmatrix}$$

$$\xrightarrow{R_1 - R_2} \begin{bmatrix} \mathbf{1} & \mathbf{0} & -\mathbf{1} & | & \mathbf{2} \\ 0 & -1 & 2 & | & -2 \\ 0 & -3 & 3 & | & 7 \end{bmatrix} \xrightarrow{R_3 - 3R_2} \begin{bmatrix} 1 & 0 & -1 & | & 2 \\ 0 & -1 & 2 & | & -2 \\ \mathbf{0} & \mathbf{0} & -\mathbf{3} & | & \mathbf{13} \end{bmatrix} \xrightarrow{(-1) \cdot R_2} \begin{bmatrix} 1 & 0 & -1 & | & 2 \\ \mathbf{0} & \mathbf{1} & -\mathbf{2} & | & \mathbf{2} \\ 0 & 0 & -3 & | & \mathbf{13} \end{bmatrix}$$

$$\xrightarrow{(-\frac{1}{3}) \cdot R_3} \begin{bmatrix} 1 & 0 & -1 & | & 2 \\ 0 & 1 & -2 & | & 2 \\ \mathbf{0} & \mathbf{0} & 1 & | & -13/3 \end{bmatrix} \xrightarrow{R_2 + 2R_3} \begin{bmatrix} 1 & 0 & -1 & | & 2 \\ \mathbf{0} & \mathbf{1} & \mathbf{0} & | & -\mathbf{20/3} \\ 0 & 0 & 1 & | & -13/3 \end{bmatrix} \xrightarrow{R_1 + R_3} \begin{bmatrix} \mathbf{1} & \mathbf{0} & \mathbf{0} & | & -\mathbf{7/3} \\ 0 & 1 & 0 & | & -20/3 \\ 0 & 0 & 1 & | & -13/3 \end{bmatrix}$$

We now convert the augmented matrix back to a system of linear equations:

$$\begin{cases} 1x - 0y + 0z = -7/3 \\ 0x - 1y + 0z = -20/3 \\ 0x - 0y + 1z = -13/3 \end{cases}$$

or more simply,

$$x = -7/3$$
$$y = -20/3$$
$$z = -13/3$$

We can check that this is a solution to the original system of equations (6).
